TEARS

Consider a 2-D dynamical system

$$\dot{w} = F(w) \iff \begin{pmatrix} \dot{x} \\ \dot{y} \end{pmatrix} = \begin{pmatrix} u(x, y) \\ v(x, y) \end{pmatrix}.$$

We can understand the flow by linearization $\dot{z} = J_F(w^*)z$.

- w^* if a fixed point, i.e. $F(w^*) = 0$
- $J_F(w^*)$ is the Jacobian matrix

$$J_F(w^*) = \begin{pmatrix} u_x(w^*) & u_y(w^*) \\ v_x(w^*) & v_y(w^*) \end{pmatrix}$$

Recall

The solutions of a linear system of differential equations $\dot{z} = Az$ are determined by the eigenvalues of A , given by λ_1 , and λ_2 .

If A is diagonalizable, then $A = P\Lambda P^{-1}$, where

$$\Lambda = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}$$

Thus the system of equations becomes

$$\dot{z} = P\Lambda P^{-1}z \quad \Longleftrightarrow \quad \begin{aligned} \dot{\phi} &= \Lambda\phi \\ \phi &= P^{-1}z \end{aligned}$$

Behavior Recognition

Linear Stability Analysis for Dynamical Systems

- Flow is described by $\dot{w} = F(w)$, with $w = (x, y)^T$ and F is obtained from the optical flow
- Linearizing about fixed points w^* gives $\dot{z} = J_F(w^*)z$.
- Behavior near the fixed points is characterized by

$$\lambda^2 - \tau\lambda + \Delta = 0 \quad \Rightarrow \quad \lambda_{1,2} = \frac{1}{2} \left(\tau \pm \sqrt{\tau^2 - 4\Delta} \right)$$

$\tau = \lambda_1 + \lambda_2$ is the trace and $\Delta = \lambda_1\lambda_2$ is the determinant

Lyapunov Exponents for Flow Segmentation

- Track movement of pixels as particle trajectories.
- Compute the distance between neighboring particles at the end of a trajectory.
- Particles that stay close together are part of the same coherent flow pattern.
- Particles that diverge belong to separate coherent flow patterns.
- Tool: Finite Time Lyapunov Exponent (FTLE)

Example Video Sequence

Particle Advection

- Every pixel has a position (x, y) .
- Optical flow provides the velocities (u, v) at each pixel.

$$\frac{dx}{dt} = u(x, y, t), \quad \frac{dy}{dt} = v(x, y, t)$$

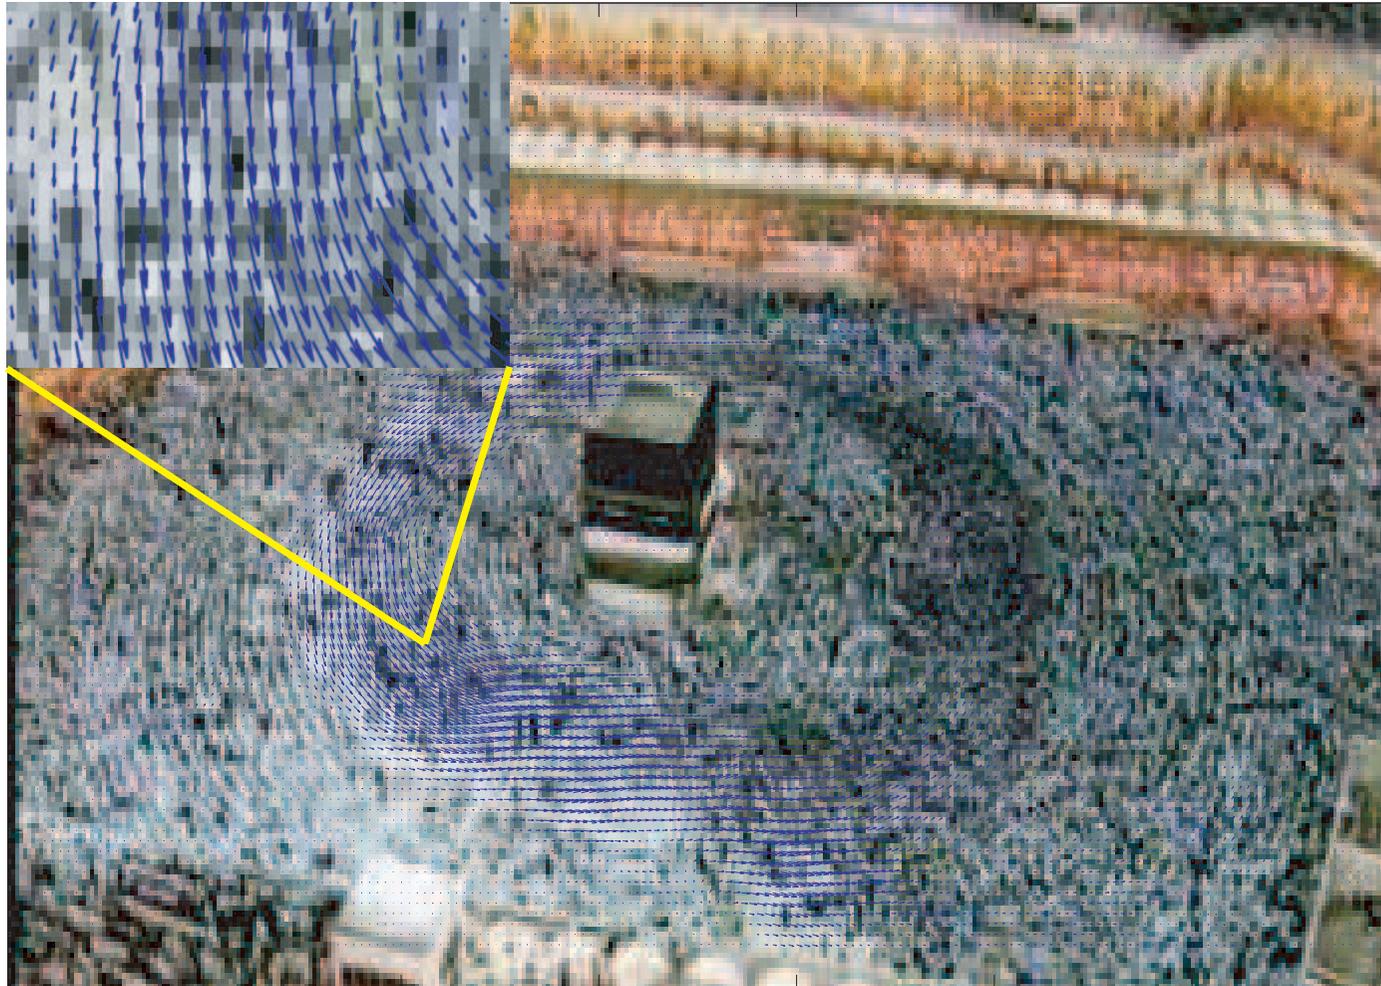

- Initial Condition: Overlay scene with a grid of particles
- Particles transported to new coordinates by time-stepping.

$$x(t + 1) = x(t) + u(x(t), y(t), t), \quad y(t + 1) = y(t) + v(x(t), y(t), t)$$

Performing computations over a time interval (≈ 60 frames) gives particle trajectories describing the motion in the scene.

Computed Particle Trajectories for Video Sequence

Computing the FTLE

The j th pair of nearest neighbors diverge at a rate L .

$$d_j(t_i) \approx k_j e^{Lt_i} \iff \ln d_j(t_i) \approx \ln k_j + Lt_i$$

- $t_i = i\Delta t$ and Δt is the sampling period
- k_j is the initial separation
- $d_j(t_i)$ denotes the distance between the j th pair of nearest neighbors after i discrete time steps.

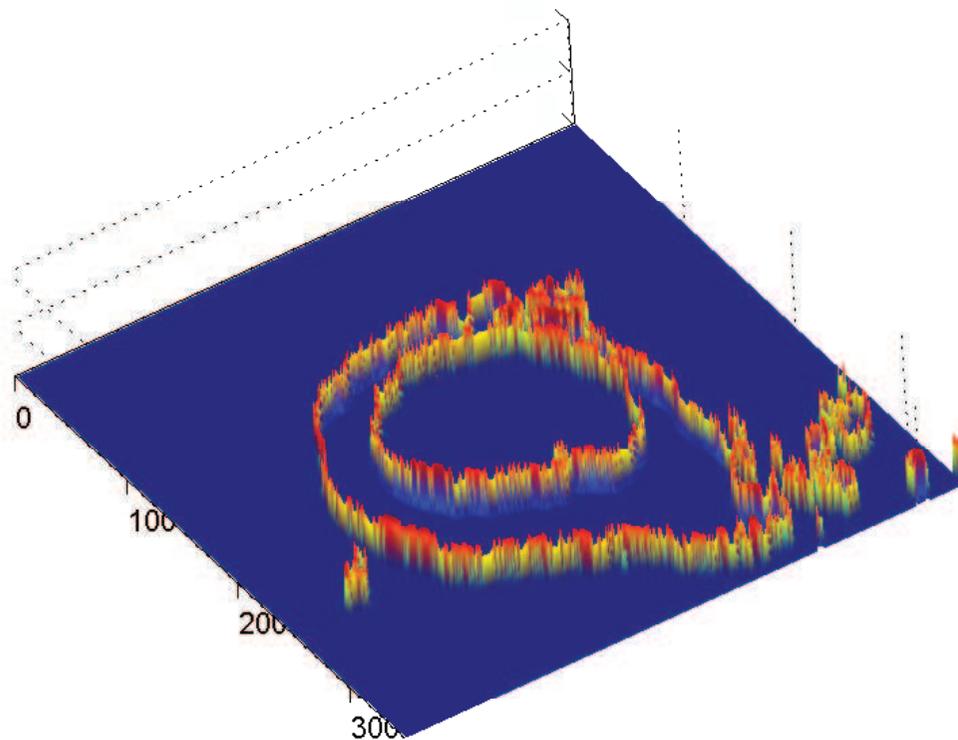

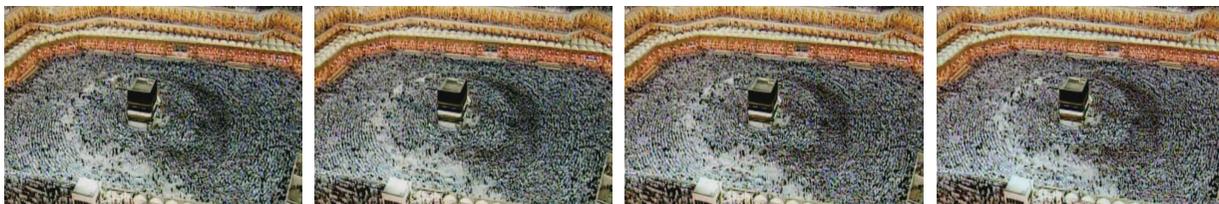

This is a set of approximately parallel lines with slope L . The largest FTLE is approximated by fitting the average line

$$a(t_i) = \frac{1}{\Delta t} \langle \ln d_j(t_i) \rangle,$$

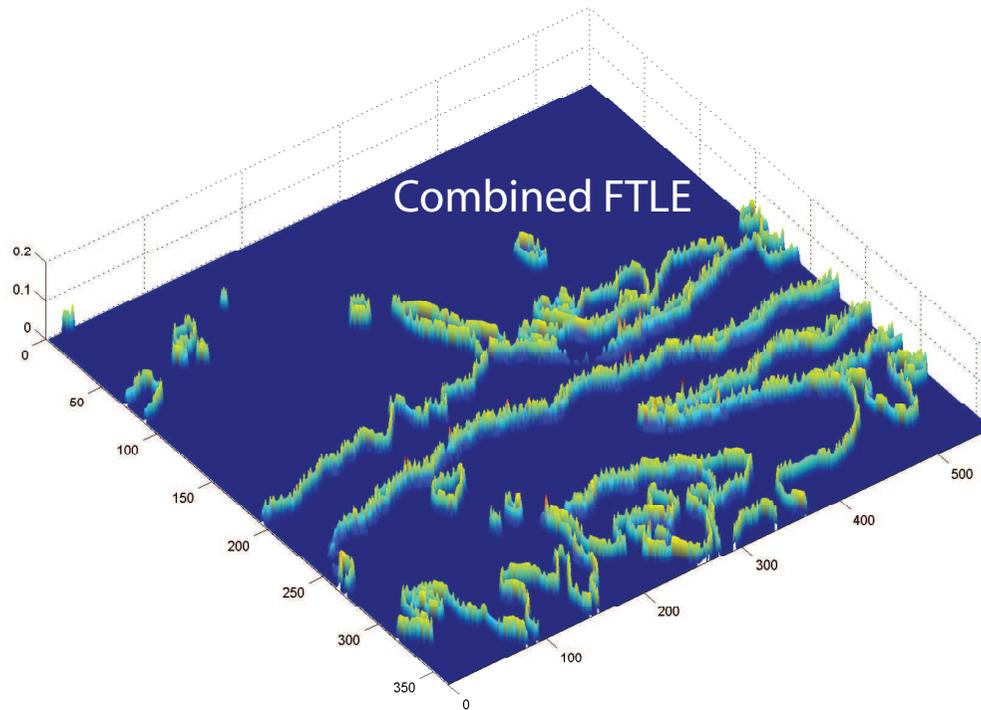

$\langle \cdot \rangle$ denotes the average over j , crucial for small/noisy data sets.

Continuous and Discrete Dynamical Systems: Pendulum Phase Portraits

$$\dot{q} \approx \frac{q(t+h) - q(t)}{h} \quad \text{and} \quad \dot{q} \approx \frac{q(t) - q(t-h)}{h}$$

$$\ddot{q} \approx \frac{d}{dt} \frac{q(t+h) - q(t)}{h} \approx \frac{1}{h} \left(\frac{q(t+h) - q(t)}{h} - \frac{q(t) - q(t-h)}{h} \right) = \frac{q(t+h) - 2q(t) + q(t-h)}{h^2}$$

Times Series Data

A time series is a sequence of numbers that represent measurements of some quantity at specific points in time.

For the discrete pendulum problem

$$x_{k+1} - 2x_k + x_{k-1} = -\sin(x_k) \text{ with } x_0 = 1 \text{ and } x_1 = 0$$

$$\begin{aligned} \mathbf{x} &= \begin{bmatrix} x_0 & x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & \dots \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & -1 & -1.159 & -0.401 & 0.747 & 1.215 & \dots \end{bmatrix} \end{aligned}$$

Phase portrait is obtained by plotting the points (x_{2j-1}, x_{2j}) .

In applications, we are given the data but not the rule. We want to extract information about the dynamics using only the data.

Discrete Dynamical Systems

In general, a discrete dynamical system has the form

$$\mathbf{z}_{n+1} = \mathbf{F}(\mathbf{z}_n) \quad \text{with specified initial condition } \mathbf{z}_0.$$

Example: The Henon Map $x_{n+1} = 1 + y_n - ax_n^2, \quad y_{n+1} = bx_n$

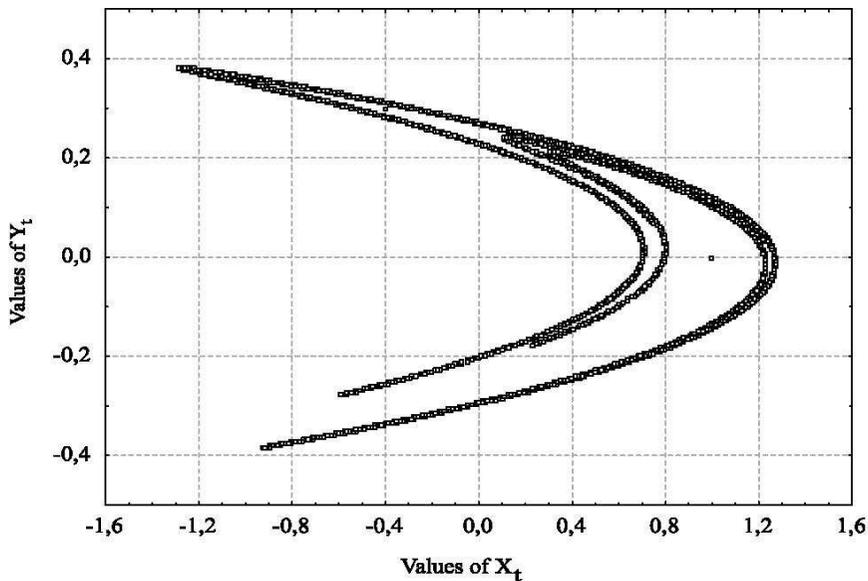

Notice:

- $\mathbf{z}_1 = \mathbf{F}(\mathbf{z}_0), \quad \mathbf{z}_2 = \mathbf{F}(\mathbf{F}(\mathbf{z}_0)), \quad \mathbf{z}_3 = \mathbf{F}(\mathbf{F}(\mathbf{F}(\mathbf{z}_0))), \quad \dots$
So it is common to use the notation $\mathbf{F}^k(\mathbf{z}) = \mathbf{F}(\mathbf{F}^{k-1}(\mathbf{z}))$
- The phase space dimension is the dimension of \mathbf{z} .
- \mathbf{z}_* is a fixed point if $\mathbf{z}_* = \mathbf{F}(\mathbf{z}_*)$.
- A linearization about the fixed point is $\mathbf{z}_{n+1} = \mathbf{J}(\mathbf{z}_*)\mathbf{z}_n$,
where $\mathbf{J}(\mathbf{z}_*)$ is the Jacobian matrix for \mathbf{F} evaluated at \mathbf{z}_* .

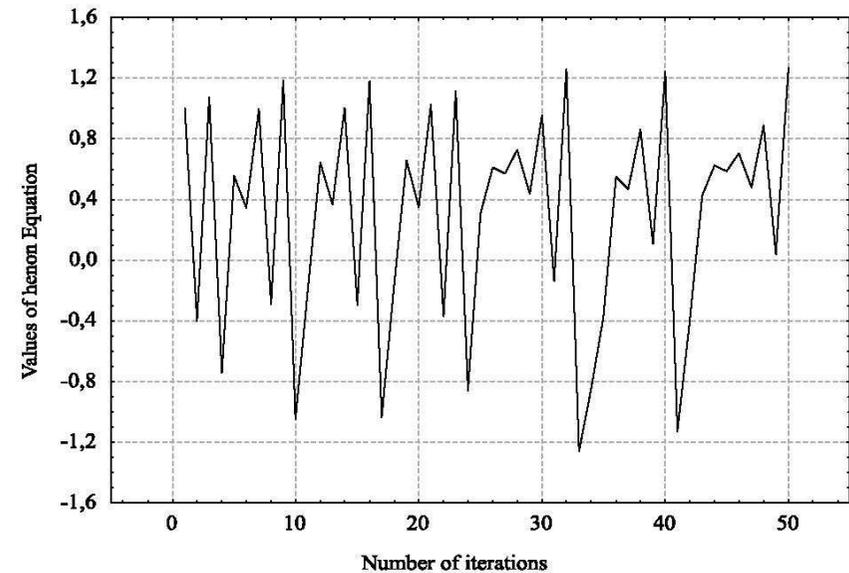

Henon Map: Time Series and Phase Portrait for

$$a = 1.4 \text{ and } b = 0.3$$

(a)

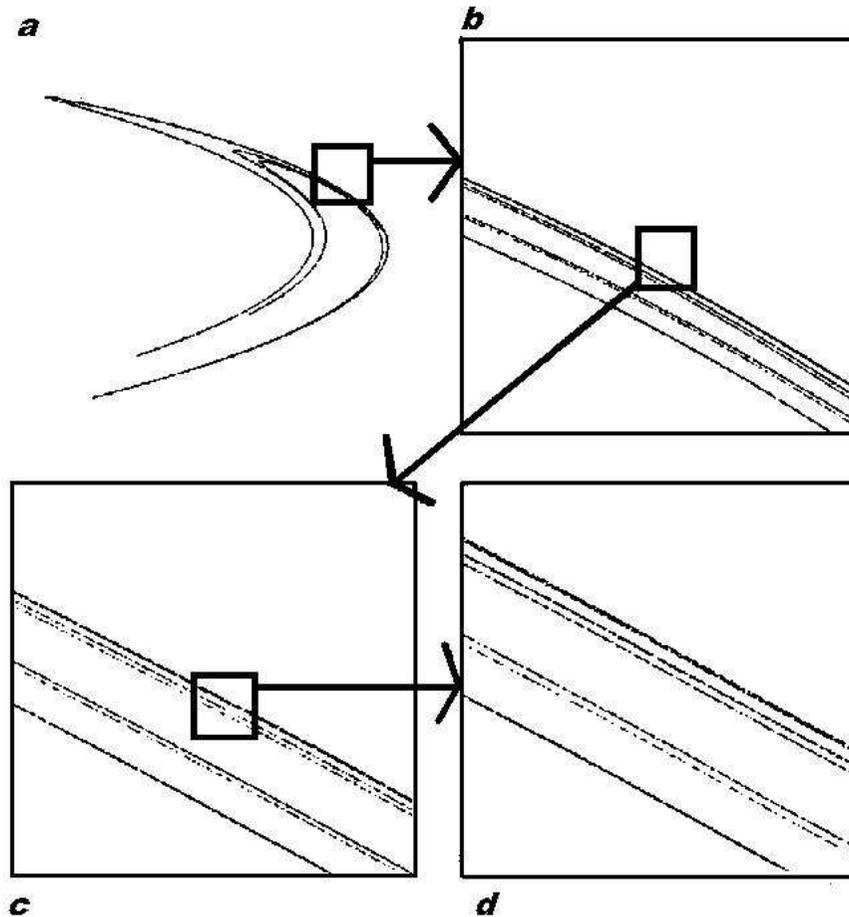

(b)

Note: A time series plot of X_t in (a) shows that the series tends to behave in an aperiodic manner. The phase diagram shows that a “banana-shaped” object appears. This is the Henon attractor, for given starting values of X_t

Phase Space Embedding

Given a time series $\mathbf{x} = \left[x_0 \ x_1 \ x_2 \ x_3 \ x_4 \ \dots \right]$ we want to find τ and m such that

$$(z_{t-\tau}, z_{t-2\tau}, \dots, z_{t-m\tau}) = \mathbf{F}(x_{t-\tau}, x_{t-2\tau}, \dots, x_{t-m\tau}).$$

- m is the dimension of phase space
- τ is known as the time delay

The function \mathbf{F} may remain unknown; as long as we have τ and m we can reconstruct phase space and compute important quantities that characterize the dynamics.

How to approximate τ and m will be revealed at a later time.

Discrete Pendulum

As a first order system

$$\dot{q} = p, \quad \dot{p} = -\sin(q)$$

In discrete form

$$q_{n+1} = q_n + hp_n, \quad p_{n+1} = p_n - h \sin(q_{n+1})$$

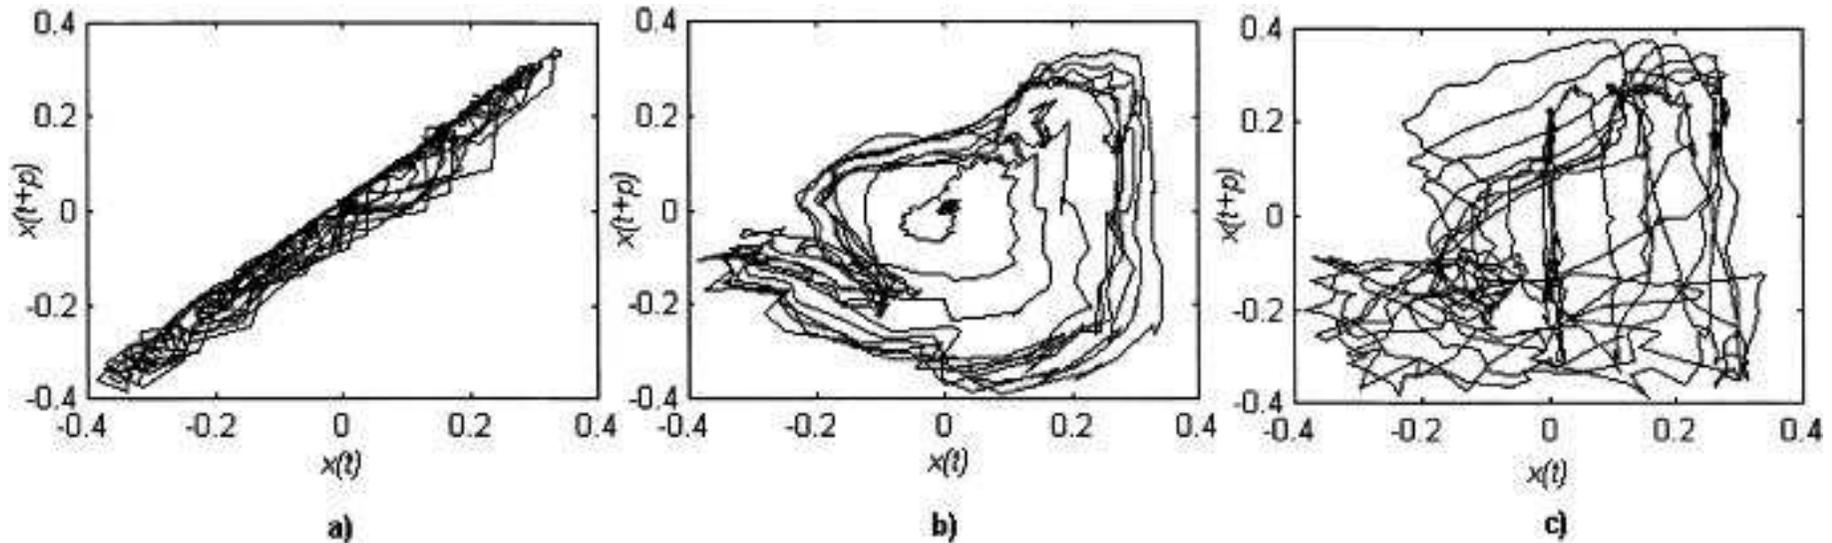

In the case of the discrete pendulum we have $\tau = 1$ and $m = 2$

$$(x_{t+1}, x_t) = (z_{t-1}, z_{t-2}) = \mathbf{F}(x_{t-1}, x_{t-2}).$$

In phase space we plot points (x_{k+1}, x_k) , because these correspond to points (q_n, p_n)

Phase Space for Varying Time Delays

- (a) time delay is too small
- (b) time delay is good
- (c) time delay is too excessive

Recurrence Plots

Given the *delay reconstruction* vectors

$$\mathbf{z}_t = (z_{t-\tau}, z_{t-2\tau}, \dots, z_{t-m\tau}),$$

we can visualize recurrence in phase space with

$$M_{i,j} = H(\epsilon - |\mathbf{z}_i - \mathbf{z}_j|).$$

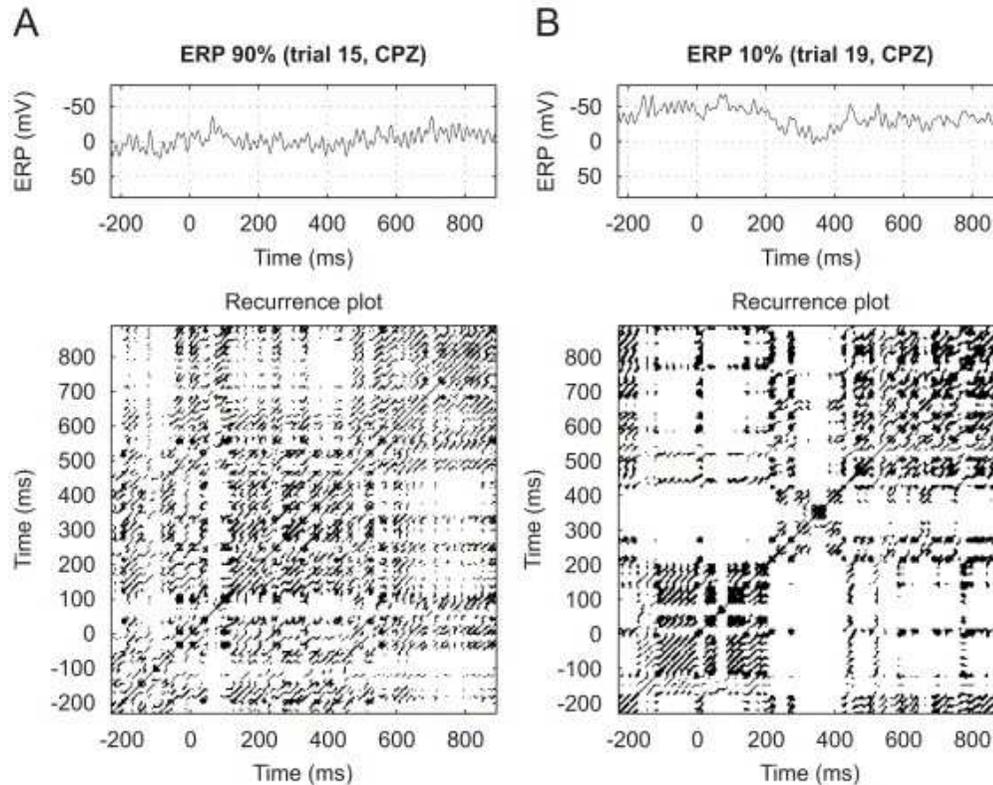

- ϵ is a chosen tolerance.

- H is the Heaviside function
$$H(x) = \begin{cases} 1 & x \geq 0 \\ 0 & x < 0 \end{cases}$$

$M_{i,j}$ is 1 if the points \mathbf{z}_i and \mathbf{z}_j are sufficiently close in phase space, 0 otherwise.

Recurrence Plot Examples

N. Marwan, M.C. Romano, M. Thiel, and J. Kurths, Recurrenceplots for the analysis of complex systems, *Physics Reports*, Volume 438, Issues 5-6, January 2007, Pages 237-329

Correlation Integral and Dimension

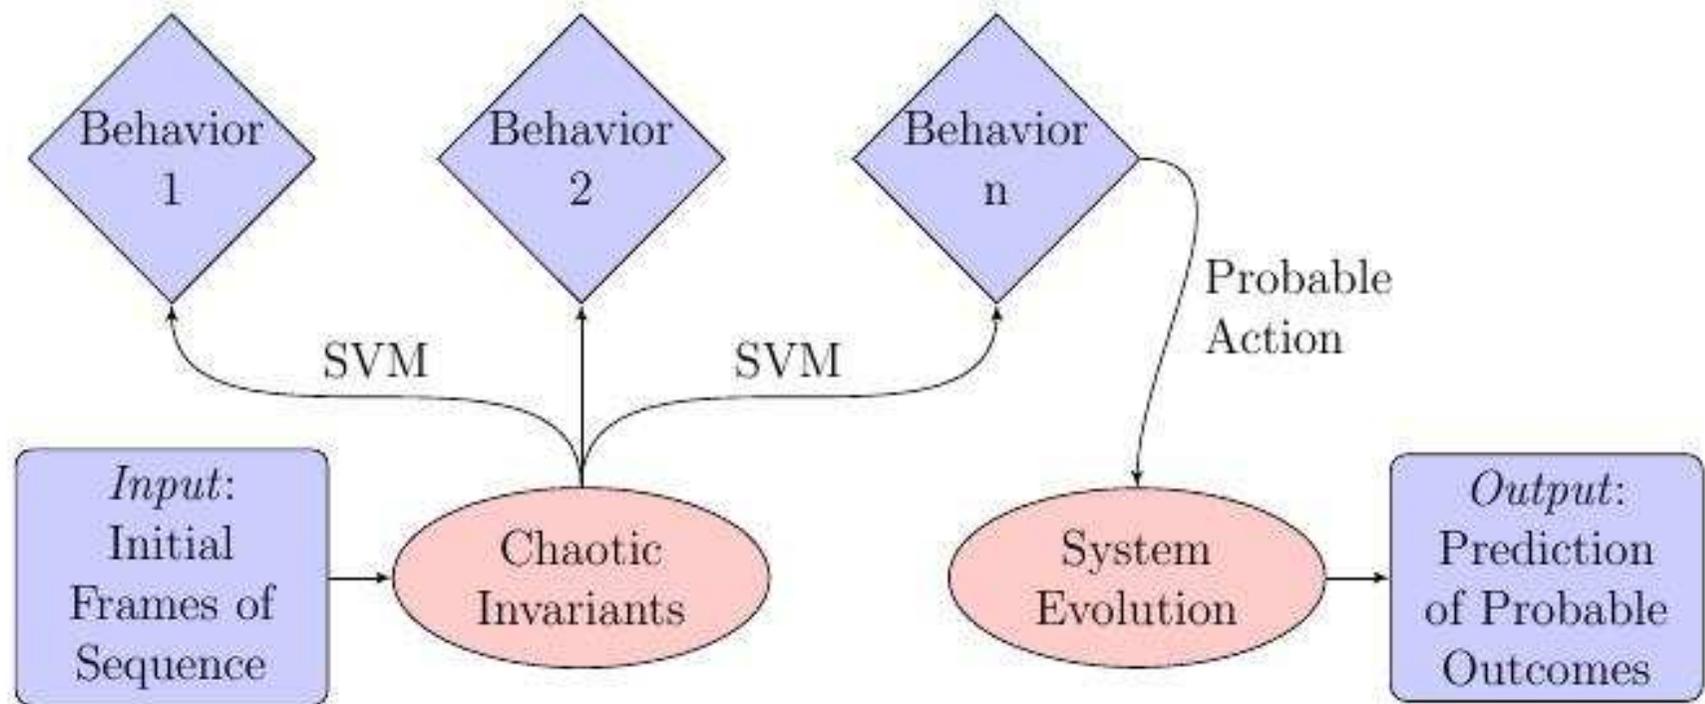

- Correlation Sum: a measure of spatial organization, giving the mean probability that states at two different times are close.

$$C(\epsilon) = \frac{1}{N^2} \sum_{i,j=1}^N H(\epsilon - \|\mathbf{z}_i - \mathbf{z}_j\|)$$

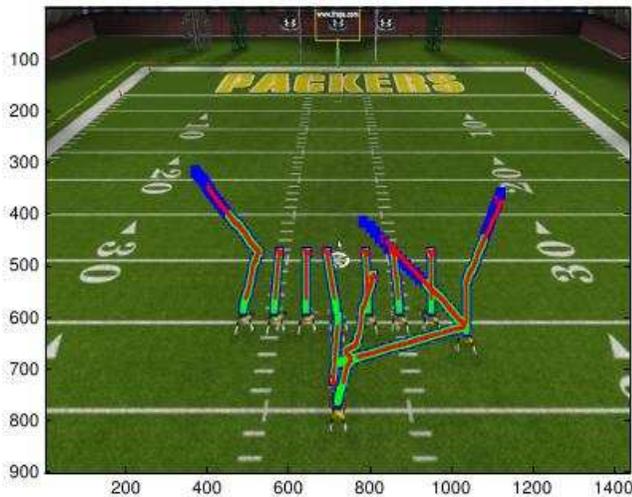

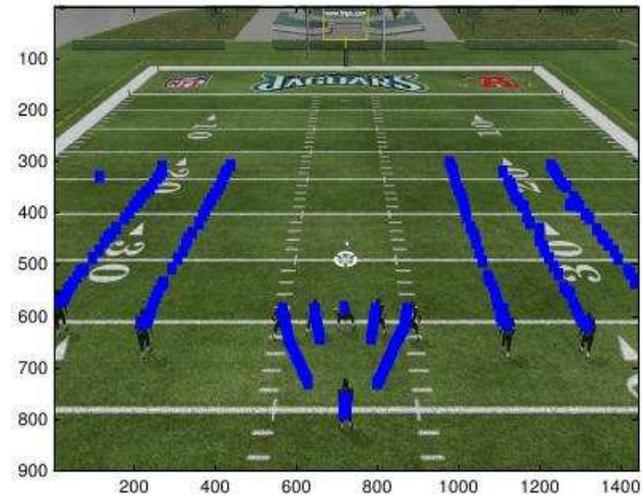

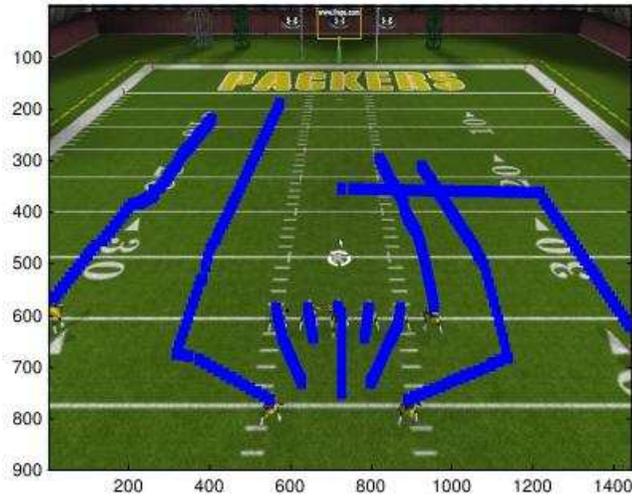

- Correlation Dimension: is effectively a measure of the size of the attractor, denoted by d , and is determined by the relation $C(\epsilon) \approx \epsilon^d$

Predicting Outcomes with Chaotic Modeling

Predicting Outcomes in Football Plays

Homework Problems

1. Use Matlab to plot different 2-dimensional phase portraits for the time series that is produced by the Henon map. Use delay times $\tau = 1, 2, \dots$ and determine which plots give the clearest information about the behavior.
2. Produce a recurrence plot for the Henon map, and compute the correlation sum and the correlation dimension.
